We place the problem of computing a Gröbner basis of a polynomial ideal within the violator space framework in order to use Clarkson’s fast sampling algorithm from geometric optimization. The framework requires three ingredients, some of which we provide theoretically, and the missing ones we provide as outputs of a machine learning algorithm. We demonstrate how this blended randomization-and-learning approach can work for symbolic computation.

Joint work with Shahrzad Jamshidi (Lake Forest College, United States) and Despina Stasi (Illinois Institute of Technology, United States).
